Author's Workbench – Deployment Report

1. Deployment Overview

Author's Workbench is a frontend web application developed using React, TypeScript and Vite. The application is deployed using GitHub Actions, with the source code maintained in GitHub.

2. Deployment Environment

Frontend: React + TypeScript

Build Tool: Vite

Source Control: GitHub

Hosting: GitHub Actions/Vercel

Build Command: npm run build

Output Directory: dist

3. Deployment Process

Before deployment, the project is checked using npm run lint, npm run test:run and npm run build. After successful checks, changes are committed and pushed to GitHub. Vercel automatically builds and deploys the updated application.

4. Continuous Deployment

GitHub and Vercel provide a basic Continuous Deployment workflow. When new code is pushed to the connected repository, Vercel automatically creates a new deployment.

5. Deployment Verification

After deployment, the application is checked to ensure that the website loads correctly, navigation works, and core functions such as project creation, deletion and chapter management operate correctly.

6. Current Limitations

The current application uses in-memory React state, so project and chapter data may be lost when the page is refreshed. Persistent storage such as IndexedDB, localStorage or a backend database can be added in future development.

7. Deployment Result

The application can be built as a Vite production application and deployed through GitHub Actions and Vercel. The workflow provides a simple and repeatable deployment process.
