Coding Standard

1. Naming & Structure

- PascalCase for components, interfaces and types.
- camelCase for functions, variables and props.
- Use descriptive names.

2. TypeScript

- Use explicit types for domain models and component props.
- Avoid `any`.
- Use `import type` for type-only imports.

3. Formatting

- Use Prettier for all TypeScript/TSX files.
- Use consistent indentation and formatting.

4. Component Design

- Components should have a single responsibility.
- Extract reusable or complex UI sections into separate components.

5. Separation of Concerns

- Keep domain/business logic in the domain layer.
- UI components should primarily handle presentation and user interaction.

6. Functions & State

- Functions should have one clear responsibility.
- React state must not be mutated directly.
- Prefer immutable state updates.

7. Documentation & Comments

- Document non-obvious business logic and design decisions.
- Avoid unnecessary comments for self-explanatory code.

8. Validation & Error Handling

- Validate user input before modifying application state.
- Handle errors explicitly and avoid silently swallowing errors.
